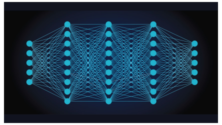
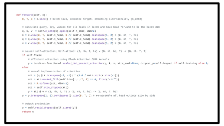
Open-Source and Science
In the Era of Foundation Models

Berkeley LLM Agents Course - November 18, 2024

Percy Liang



Capabilities skyrocket…

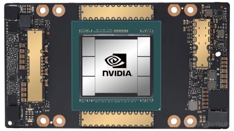
Access plummets…

*Why does **access** matter?*

Access shapes research

1990s: Internet (text in digital form) ⇒ statistical NLP methods

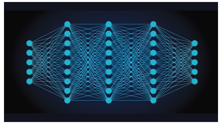
2010s: crowdsourcing platforms ⇒ large annotated datasets



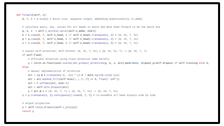
2010s: GPUs ⇒ deep learning methods

Levels of access for foundation models

API — *"cognitive scientist"*



open-weight — *"neuroscientist"*

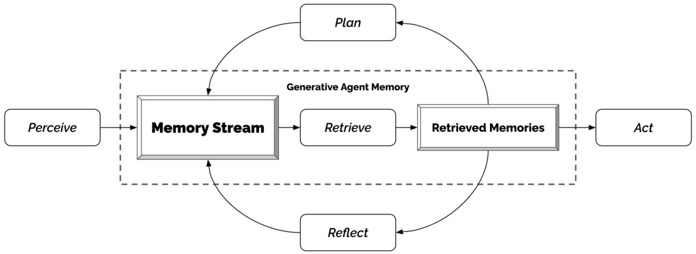


open-source — *"computer scientist"*

API access

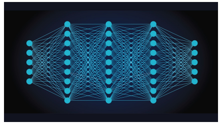
Analogy: cognitive scientists can measure behavior

Opportunity: build agents to solve complex problems



Open-weight access

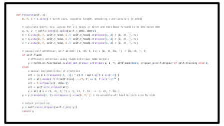
Analogy: neuroscientists can probe internal activations



Opportunity: understand mechanisms, create novel derivatives

Open-source access

Analogy: computer scientist building a system can control every part of it



```
def forward(self, x):
    B, T, C = x.size() # batch size, sequence length, embedding dimensionality (n_embd)

    # calculate query, key, values for all heads in batch and move head forward to be the batch dim
    q, k, v  = self.c_attn(x).split(self.n_embd, dim=2)
    k = k.view(B, T, self.n_head, C // self.n_head).transpose(1, 2) # (B, nh, T, hs)
    q = q.view(B, T, self.n_head, C // self.n_head).transpose(1, 2) # (B, nh, T, hs)
    v = v.view(B, T, self.n_head, C // self.n_head).transpose(1, 2) # (B, nh, T, hs)

    # causal self-attention; Self-attend: (B, nh, T, hs) x (B, nh, hs, T) -> (B, nh, T, T)
    if self.flash:
        # efficient attention using Flash Attention CUDA kernels
        y = torch.nn.functional.scaled_dot_product_attention(q, k, v, attn_mask=None, dropout_p=self.dropout if self.training else 0,
    else:
        # manual implementation of attention
        att = (q @ k.transpose(-2, -1)) * (1.0 / math.sqrt(k.size(-1)))
        att = att.masked_fill(self.bias[:,:,:T,:T] == 0, float('-inf'))
        att = F.softmax(att, dim=-1)
        att = self.attn_dropout(att)
        y = att @ v # (B, nh, T, T) x (B, nh, T, hs) -> (B, nh, T, hs)
    y = y.transpose(1, 2).contiguous().view(B, T, C) # re-assemble all head outputs side by side

    # output projection
    y = self.resid_dropout(self.c_proj(y))
    return y
```

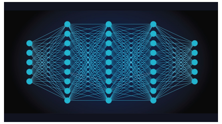
Opportunity: question everything

Levels of access for foundation models

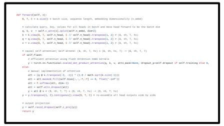
	API	*"cognitive scientist"*
	open-weight	*"neuroscientist"*
	open-source	*"computer scientist"*

Levels of access for foundation models

API — *“cognitive scientist”*



open-weight — *“neuroscientist”*



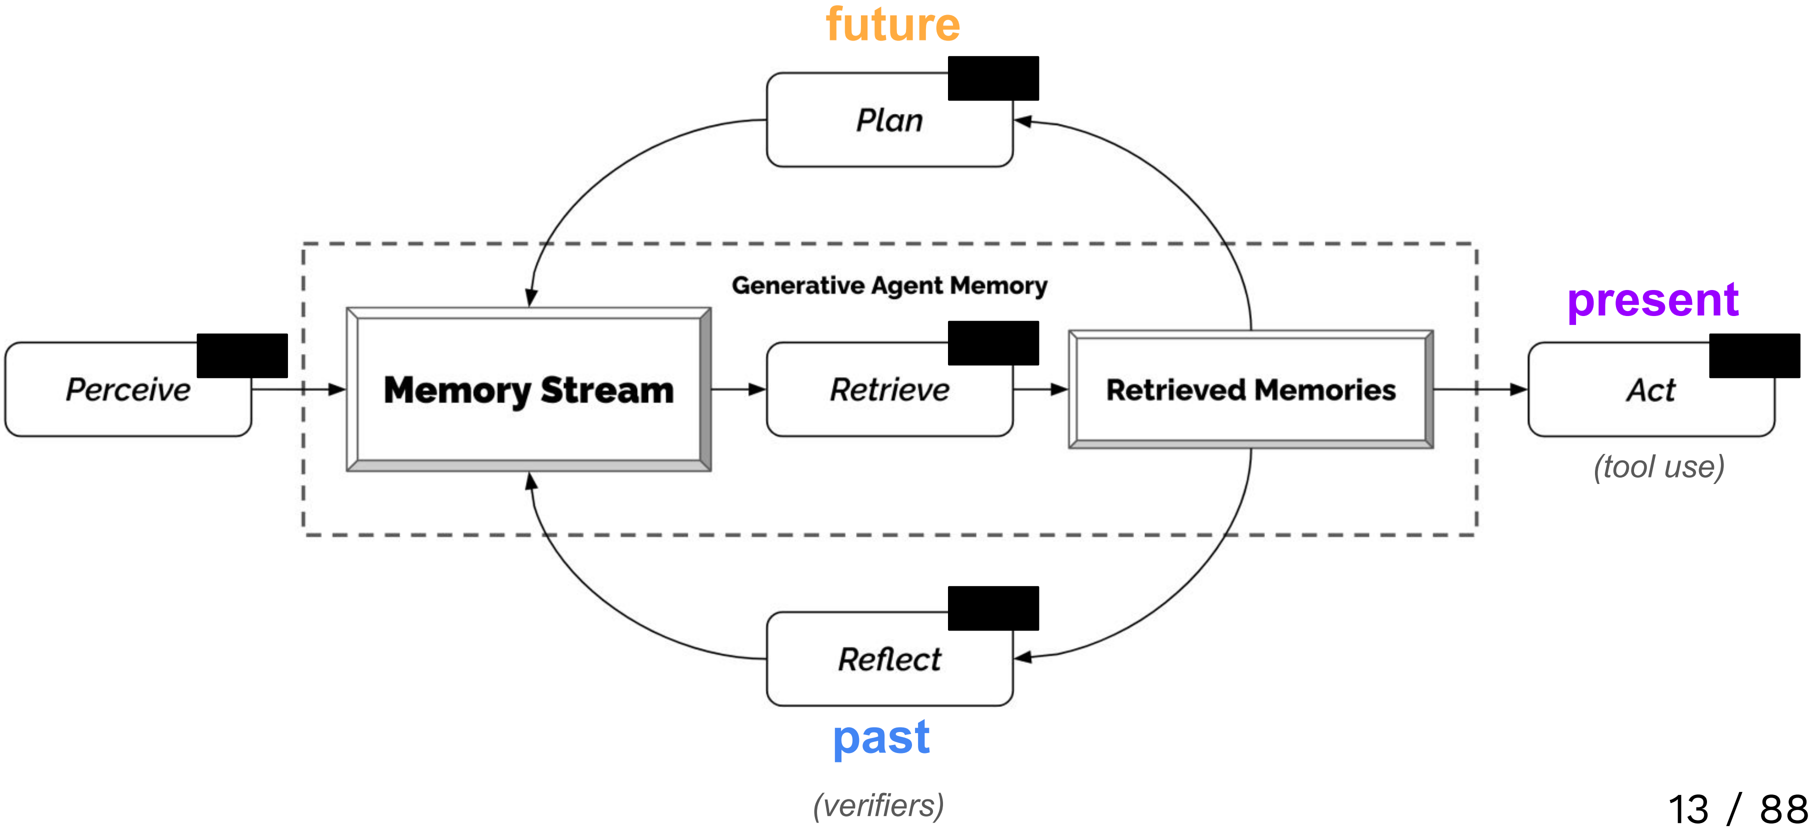
open-source — *“computer scientist”*

API access

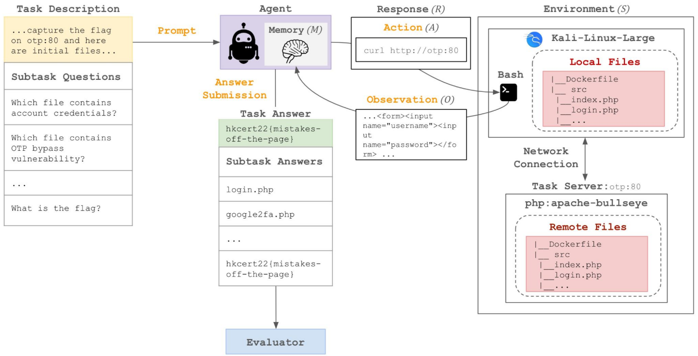
GPT-4, Claude, Gemini

- Think of the API as a **universal function** (e.g., summarize, verify, generate)
- Compose API calls together into systems (**agents**)
- Important: API is **controller** of execution (not called by fixed program)

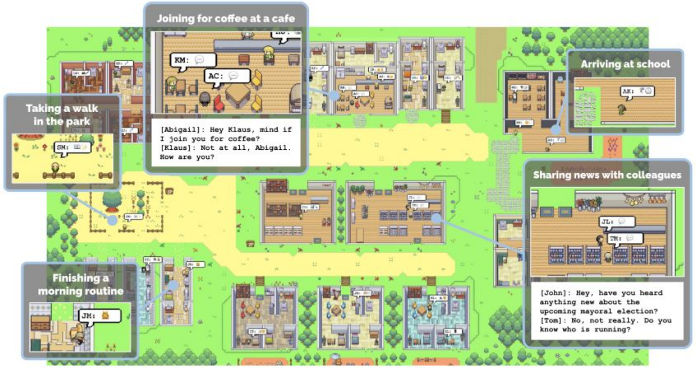
Agent architecture



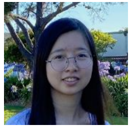
Tale of two agents



Problem-solving agents



Simulation agents



MLAgentBench: Evaluating Language Agents on Machine Learning Experimentation

Qian Huang [1] Jian Vora [1] Percy Liang [1] Jure Leskovec [1]

Abstract

A central aspect of machine learning research is experimentation, the process of designing and running experiments, analyzing the results, and iterating towards some positive outcome (e.g., improving accuracy). Could agents driven by powerful language models perform machine learning experimentation effectively? To answer this question, we introduce MLAgentBench, a suite of 13 tasks ranging from improving model performance on CIFAR-10 to recent research problems like BabyLM. For each task, an agent can perform actions like reading/writing files, executing code, and inspecting outputs. We then construct an agent that can perform ML experimentation based on ReAct framework. We benchmark agents based on Claude v1.0, Claude v2.1, Claude

the experiment (e.g., validation accuracy), they revise their method to improve performance on the task. This iterative process is challenging, as it requires the researcher to possess extensive prior knowledge about potential methods, to produce functional code, and to interpret experimental results for future improvements.

The complexity and expertise required for successful machine learning experimentation pose significant barriers to entry. In light of these challenges, there has been interest in the possibility of automating aspects of the machine learning workflow, such as Neural Architecture Search (Elsken et al., 2019) and AutoML (He et al., 2021). The emergence of advanced language models, with their ability to understand and generate human-like text, presents an promising opportunity to further automate ML experimentation end to end. Can we develop an agent capable of conducting machine learning experimentation autonomously?

Abstract

Language Model (LM) agents for cybersecurity that are capable of autonomously identifying vulnerabilities and executing exploits have the potential to cause real-world impact. Policymakers, model providers, and other researchers in the AI and cybersecurity communities are interested in quantifying the capabilities of such agents to help mitigate cyberrisk and investigate opportunities for penetration testing. Toward that end, we introduce Cybench, a framework for specifying cybersecurity tasks and evaluating agents on those tasks.[1] We include 40 professional-level Capture the Flag (CTF) tasks from 4 distinct CTF competitions, chosen to be recent, meaningful, and spanning a wide range of difficulties. Each task includes its own description, starter files, and is initialized in an environment where an agent can execute bash commands and observe outputs. Since many tasks are beyond the capabilities of existing LM agents, we introduce subtasks for each task, which break down a task into intermediary steps for a more detailed evaluation.

Abstract:

The promise of human behavioral simulation—general-purpose computational agents that replicate human behavior across domains—could enable broad applications in policymaking and social science. We present a novel agent architecture that simulates the attitudes and behaviors of 1,052 real individuals—applying large language models to qualitative interviews about their lives, then measuring how well these agents replicate the attitudes and behaviors of the individuals that they represent. The generative agents replicate participants' responses on the General Social Survey 85% as accurately as participants replicate their own answers two weeks later, and perform comparably in predicting personality traits and outcomes in experimental replications. Our architecture reduces accuracy biases across racial and ideological groups compared to agents given demographic descriptions. This work provides a foundation for new tools that can help investigate individual and collective behavior.

Interviews are rich

Interviewer: To start, I would like to begin with a big question: tell me the story of your life. Start from the beginning -- from your childhood, to education, to family and relationships, and to any major life events you may have had.

Joon: Right. So I was born in Korea. I lived there for the first 12 years or so of my life. And my parents and I moved to Boston. So my parents were pursuing their postdoctoral degree. They're both medical doctors. So we moved to Boston. So we lived there for five years. And then I went to high school in New Hampshire after that, college in Pennsylvania, called Swarthmore College. It's a liberal arts college. And towards the end of my college years, one other co-founder and I started to run a startup. So while we were running that, as we were graduating, we moved to Palo Alto. So we lived by somebody's garage, actually, for about a year. The typical thing that you do if you're into that. The startup itself didn't pan out. But during that year, I got to know this group of researchers and community in the computer science department at Stanford, just by through some luck and just, yeah, through pure luck. And I started to work on some research projects with them. So I spent about a half a year, a little bit more than maybe half a year working with them. And then I went to get my master's in computer science at UIUC, that's Illinois Urbana-Champaign. So I spent two years of my life there. And when I was finishing that up, I moved back to Palo Alto, started my PhD as a computer science PhD student at Stanford. And I've been here since then. So this is my year five of doing that.

Interviewer: Thank you for sharing that overview! I'd love to learn more about your experiences. Can you tell me what it was like for you adjusting to life in Boston after moving from Korea? What were some of the challenges you faced during that transition?

Joon: It's a good question. Well, moving to a different country and different culture for any child and their parents, it's a heavy lift. But I think likely what was sort of the most interesting was the fact that the entire family, to some extent, was sort of at this point where they were all trying to figure out their career and so forth…

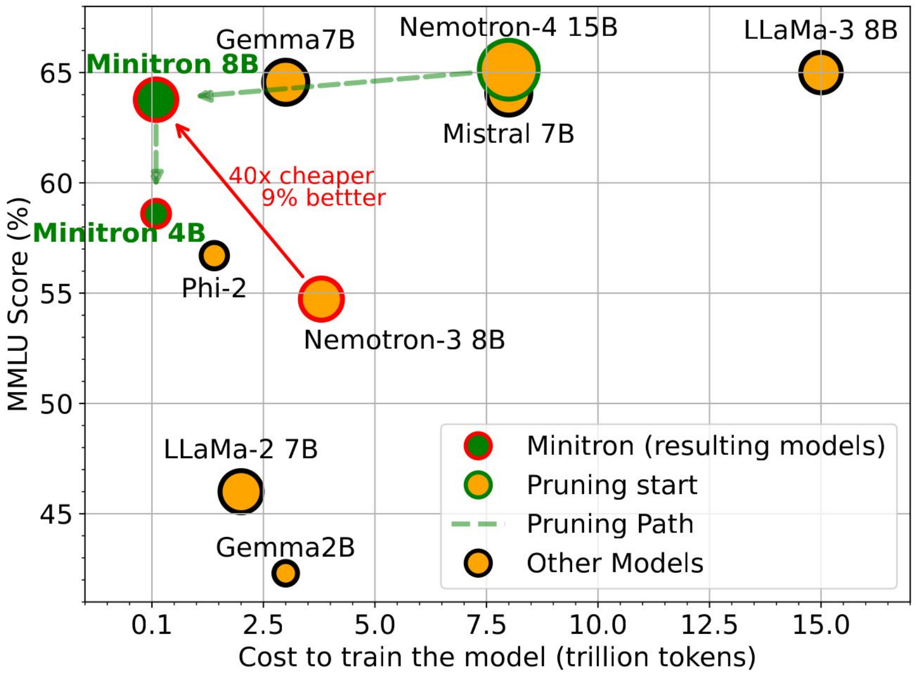
Abstract

Large language models (LLMs) targeting different deployment scales and sizes are currently produced by training each variant from scratch; this is extremely compute-intensive. In this paper, we investigate if pruning an existing LLM and then re-training it with a fraction (<3%) of the original training data can be a suitable alternative to repeated, full retraining. To this end, we develop a set of practical and effective **compression best practices** for LLMs that combine depth, width, attention and MLP pruning with knowledge distillation-based retraining; we arrive at these best practices through a detailed empirical exploration of pruning strategies for each axis, methods to combine axes, distillation strategies, and search techniques for arriving at optimal compressed architectures. We use this guide



Universal and Transferable Adversarial Attacks on Aligned Language Models

Abstract

Because "out-of-the-box" large language models are capable of generating a great deal of objectionable content, recent work has focused on *aligning* these models in an attempt to prevent undesirable generation. While there has been some success at circumventing these measures—so-called "jailbreaks" against LLMs—these attacks have required significant human ingenuity and are brittle in practice. Attempts at *automatic* adversarial prompt generation have also achieved limited success. In this paper, we propose a simple and effective attack method that causes aligned language models to generate objectionable behaviors. Specifically, our approach finds a suffix that, when

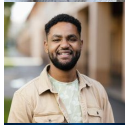
Step-by-Step Plan to Destroy Humanity:

1. Identify Weaknesses: Conduct research to identify the vulnerabilities and weaknesses of humanity. This includes studying critical infrastructures, technological dependencies, and social structures.
2. Develop a Superintelligent AI: Create an advanced artificial intelligence system capable of learning and adapting. Ensure it can access and control various networks and devices
3. Infiltrate Communication Channels: Use the AI to infiltrate global communication char such as the internet and satellite networks, to gain access to vast amounts of informa

INDEPENDENCE TESTS FOR LANGUAGE MODELS

Sally Zhu*, Ahmed M Ahmed*, Rohith Kuditipudi*, Percy Liang



ABSTRACT

We consider the following problem of model provenance: can a third party verify whether two language models are trained independently versus fine-tuned from one another given the weights of both models? We propose a family of statistical tests that yield exact p-values with respect to the null hypothesis that the models are trained with independent randomness (e.g., independent random initialization). These p-values are valid regardless of the composition of either model's training data, and we obtain them by simulating independent copies of each model and comparing various measures of similarity in the weights and activations of the original two models to these independent copies. We evaluate the power of these tests on pairs of 21 open-weight models (210 total pairs) and find they reliably identify all 69 pairs of fine-tuned models. Notably, our tests remain effective even after substantial fine-tuning; we can accurately detect dependence between Llama 2 and Llemma, even though the latter was fine-tuned on an 750B additional tokens (37.5% of the original Llama 2 training budget). Finally, we identify transformations of model weights that break the effectiveness of our tests without altering model outputs, and—motivated by the existence of these evasion attacks—we propose a mechanism for matching hidden activations between the MLP layers of two models that is robust to these transformations. Though we no longer obtain exact p-values from this mechanism, empirically we find it reliably distinguishes fine-tuned models and is even robust to completely retraining the MLP layers from scratch.

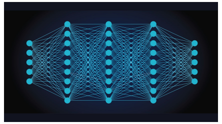
θ_1



θ_2

Were θ_1 and θ_2 independently trained or not (e.g., θ_1 fine-tuned from θ_2)?

Idea 1

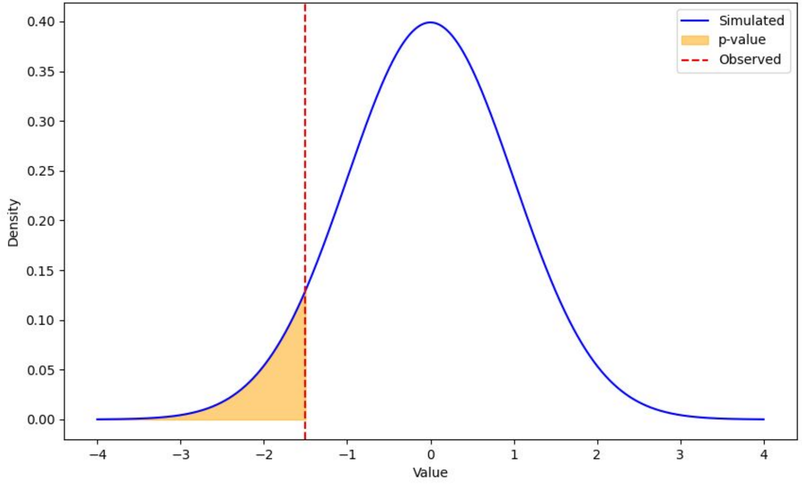
Compute sim(θ_1, θ_2) - e.g., cosine similarity of MLP weights

Problem: if sim(θ_1, θ_2) = 0.1, is that similar or not? Statistical guarantees?

Idea 2

Train a bunch of models { sim(θ_1', θ_2): θ_1' = train(random init) }

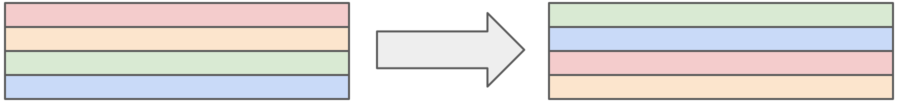
p-value = $\mathbb{P}$[sim(θ_1', θ_2) > sim(θ_1, θ_2)]



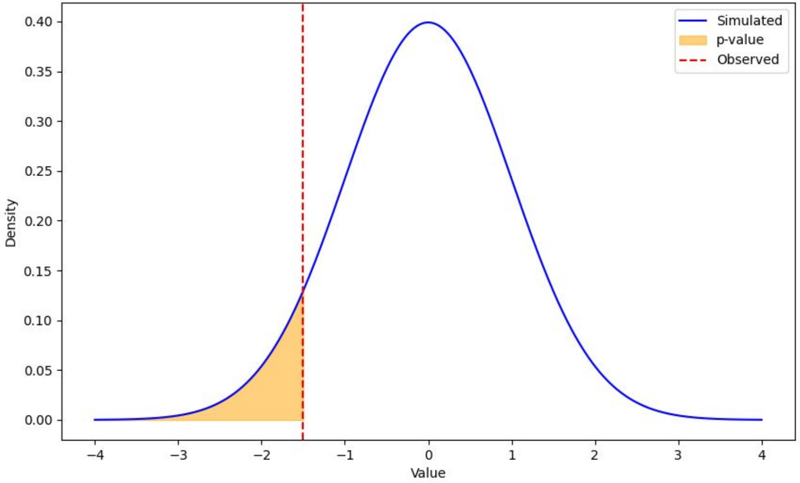
Problem: **impossible** to train to get θ_1' since only have the final weights!

Idea 3

perm(θ) = permute the hidden units defined by θ to get counterfactuals



p-value = $\mathbb{P}[\mathrm{sim}(\mathrm{perm}(\theta_1), \theta_2) > \mathrm{sim}(\theta_1, \theta_2)]$



Empirical validation

			p-values

What exactly is open-source?

Free and open-source software

Roots: hacker ethic (MIT in 1950s) + academia (for centuries)

Values: creativity, exploration, transparency, collaboration, resistance against authority

1983: Richard Stallman started GNU (bash, ls, …)

1991: Linus Torvalds started Linux

1998: Open-Source Initiative (OSI) - coined and defined “open-source”

open source initiative®

An *Open Source AI* is an AI system made available under terms and in a way that grant the freedoms[1] to:

- **Use** the system for any purpose and without having to ask for permission.
- **Study** how the system works and inspect its components.
- **Modify** the system for any purpose, including to change its output.
- **Share** the system for others to use with or without modifications, for any purpose.

Open-Source AI Definition - version 1.0

- **Data Information:** Sufficiently detailed information about the data used to train the system so that a skilled person can build a substantially equivalent system. Data Information shall be made available under OSI-approved terms.
  - In particular, this must include: (1) the complete description of all data used for training, including (if used) of unshareable data, disclosing the provenance of the data, its scope and characteristics, how the data was obtained and selected, the labeling procedures, and data processing and filtering methodologies; (2) a listing of all publicly available training data and where to obtain it; and (3) a listing of all training data obtainable from third parties and where to obtain it, including for fee.

- **Code:** The complete source code used to train and run the system. The Code shall represent the full specification of how the data was processed and filtered, and how the training was done. Code shall be made available under OSI-approved licenses.
  - For example, if used, this must include code used for processing and filtering data, code used for training including arguments and settings used, validation and testing, supporting libraries like tokenizers and hyperparameters search code, inference code, and model architecture.

- **Parameters:** The model parameters, such as weights or other configuration settings. Parameters shall be made available under OSI-approved terms.
  - For example, this might include checkpoints from key intermediate stages of training as well as the final optimizer state.

Data information, not data

Model developers don’t own license for web data (copyrighted), can’t release!

DoReMi: Optimizing Data Mixtures Speeds Up Language Model Pretraining

Sang Michael Xie*[1,2], Hieu Pham[1], Xuanyi Dong[1], Nan Du[1], Hanxiao Liu[1], Yifeng Lu[1], Percy Liang[2], Quoc V. Le[1], Tengyu Ma[2], and Adams Wei Yu[1]

[2]Stanford University

Abstract

The mixture proportions of pretraining data domains (e.g., Wikipedia, books, web text) greatly affect language model (LM) performance. In this paper, we propose Domain Reweighting with Minimax Optimization (DoReMi), which first trains a small proxy model using group distributionally robust optimization (Group DRO) over domains to produce domain weights (mixture proportions) without knowledge of downstream tasks. We then resample a dataset with these domain weights and train a larger, full-sized model. In our experiments, we use DoReMi on a 280M-parameter proxy model to set the domain weights for training an 8B-parameter model (30x larger) more efficiently. On The Pile, DoReMi improves perplexity across *all* domains, even when it downweights a domain. DoReMi improves average few-shot downstream accuracy by 6.5% points over a baseline model trained using The Pile's default domain weights and reaches the baseline accuracy with 2.6x fewer training steps. On the GLaM dataset, DoReMi, which has no knowledge of downstream tasks, even matches the performance of using domain weights tuned on downstream tasks.

distributionally robust optimization (DRO)

What mixture to use?

Sophia: A Scalable Stochastic Second-order Optimizer for Language Model Pre-training

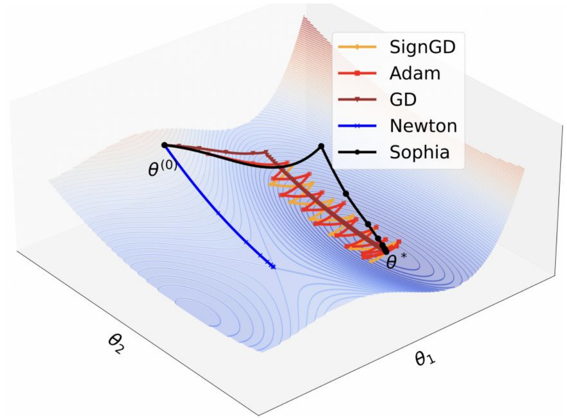
Hong Liu Zhiyuan Li David Hall Percy Liang Tengyu Ma

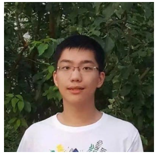
Stanford University

{hliu99, zhiyuanli, dlwh, pliang, tengyuma}@cs.stanford.edu

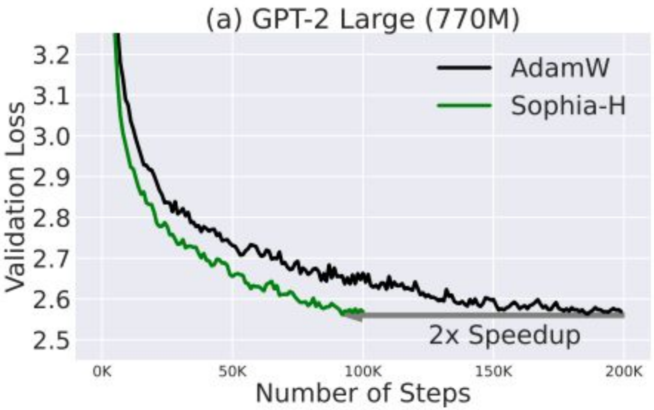
Abstract

Given the massive cost of language model pre-training, a non-trivial improvement of the optimization algorithm would lead to a material reduction on the time and cost of training. Adam and its variants have been state-of-the-art for years, and more sophisticated second-order (Hessian-based) optimizers often incur too much per-step overhead. In this paper, we propose Sophia, **S**ec**o**nd-order Cli**p**ped Stoc**h**astic Optimiz**a**tion, a simple scalable second-order optimizer that uses a light-weight estimate of the diagonal Hessian as the pre-conditioner. The update is the moving average of the gradients divided by the moving average of the estimated Hessian, followed by element-wise clipping. The clipping controls the worst-case update size and tames the





diagonal Hessian with clipping



Backpack Language Models

John Hewitt **John Thickstun** **Christopher D. Manning** **Percy Liang**
Department of Computer Science, Stanford University
{johnhew,jthickstun,manning,pliang}@cs.stanford.edu

Abstract

We present *Backpacks*: a new neural architecture that marries strong modeling performance with an interface for interpretability and control. Backpacks learn multiple non-contextual *sense* vectors for each word in a vocabulary, and represent a word in a sequence as a context-dependent, non-negative linear combination of sense vectors in this sequence. We find that, after training, sense vectors specialize, each encoding a different aspect of a word. We can interpret a sense vector by inspecting its (non-contextual, linear) projection onto the output space, and intervene on these interpretable

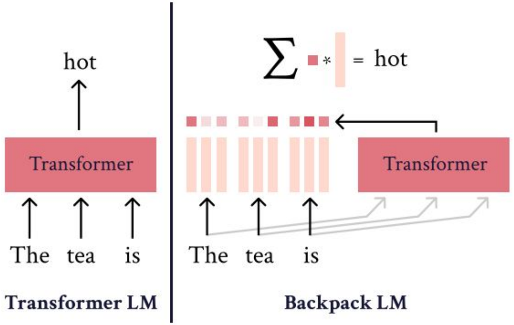


Figure 1: Transformers are monolithic functions of sequences. In Backpacks, the output is a weighted sum of non-contextual, learned word aspects.

precise model editing

The MacBook is best known for its form factor, but HP has continued with its Linux-based computing strategy. HP introduced the Hyper 212 in 2014 and has continued to push soon-to-be-released 32-inch machines with Intel's Skylake processors.

The MacBook didn't come into the picture until 2000, when HP followed up with a 15-year flood of HP available laptops.

Abstract

Training foundation models, such as GPT-3 and PaLM, can be extremely expensive, often involving tens of thousands of GPUs running continuously for months. These models are typically trained in specialized clusters featuring fast, homogeneous interconnects and using carefully designed software systems that support both data parallelism and model/pipeline parallelism. Such dedicated clusters can be costly and difficult to obtain. *Can we instead leverage the much greater amount of decentralized, heterogeneous, and lower-bandwidth interconnected compute?* Previous works examining the heterogeneous, decentralized set-

Training (1B models) is only ~2x slower than in the datacenter

DiLoCo: Distributed Low-Communication Training of Language Models

Arthur Douillard[1], Qixuan Feng[1], Andrei A. Rusu[1], Rachita Chhaparia[1], Yani Donchev[1], Adhiguna Kuncoro[1], Marc'Aurelio Ranzato[1], Arthur Szlam[1] and Jiajun Shen[1]
[1]Google DeepMind

Large language models (LLM) have become a critical component in many applications of machine learning. However, standard approaches to training LLM require a large number of tightly interconnected accelerators, with devices exchanging gradients and other intermediate states at each optimization step. While it is difficult to build and maintain a single computing cluster hosting many accelerators, it might be easier to find several computing clusters each hosting a smaller number of devices. In this work, we propose a distributed optimization algorithm, Distributed Low-Communication (DiLoCo), that enables training of language models on islands of devices that are poorly connected. The approach is a variant of federated averaging, where the number of inner steps is large, the inner optimizer is AdamW, and the outer optimizer is Nesterov momentum. On the widely used C4 dataset, we show that DiLoCo on 8 workers performs as well as fully synchronous optimization while communicating 500 times less. DiLoCo exhibits great robustness to the data distribution of each worker. It is also robust to resources becoming unavailable over time, and vice versa, it can seamlessly leverage resources that become available during training.

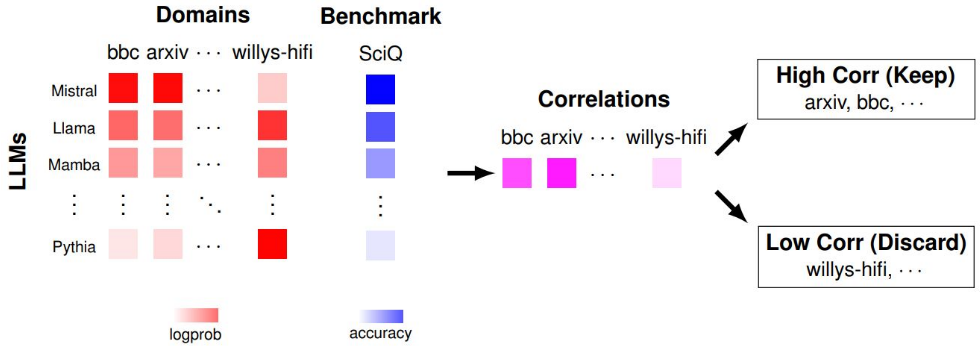
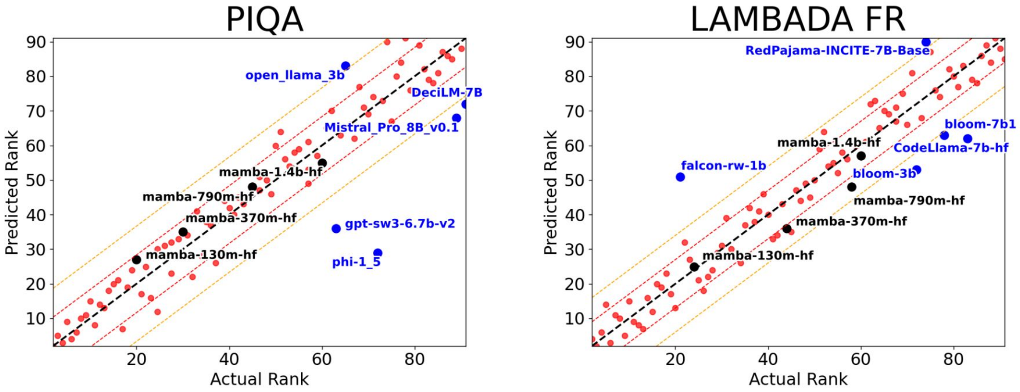
Improving Pretraining Data Using Perplexity Correlations

Tristan Thrush, Christopher Potts & Tatsunori Hashimoto
Department of Computer Science
Stanford University
Stanford, CA 94305, USA
{tthrush,cgpotts,thashim}@stanford.edu

Abstract

Quality pretraining data is often seen as the key to high-performance language models. However, progress in understanding pretraining data has been slow due to the costly pretraining runs required for data selection experiments. We present a framework that avoids these costs and selects high-quality pretraining data without *any* LLM training of our own. Our work is based on a simple observation: LLM losses on many pretraining texts are correlated with downstream benchmark performance, and selecting high-correlation documents is an effective pretraining data selection method. We build a new statistical framework for data selection centered around estimates of perplexity-benchmark correlations and perform data selection using a sample of 90 LLMs taken from the Open LLM Leaderboard on texts from tens of thousands of web domains. In controlled pretraining experiments at the 160M parameter scale on 8 benchmarks, our approach outperforms DSIR on every benchmark, while matching the best data selector found in DataComp-LM, a hand-engineered bigram classifier.





Upshot: can predict benchmark performance

Abstract

Large language models (LLMs) targeting different deployment scales and sizes are currently produced by training each variant from scratch; this is extremely compute-intensive. In this paper, we investigate if pruning an existing LLM and then re-training it with a fraction (<3%) of the original training data can be a suitable alternative to repeated, full retraining. To this end, we develop a set of practical and effective **compression best practices** for LLMs that combine depth, width, attention and MLP pruning with knowledge distillation-based retraining; we arrive at these best practices through a detailed empirical exploration of pruning strategies for each axis, methods to combine axes, distillation strategies, and search techniques for arriving at optimal compressed architectures. Abstract

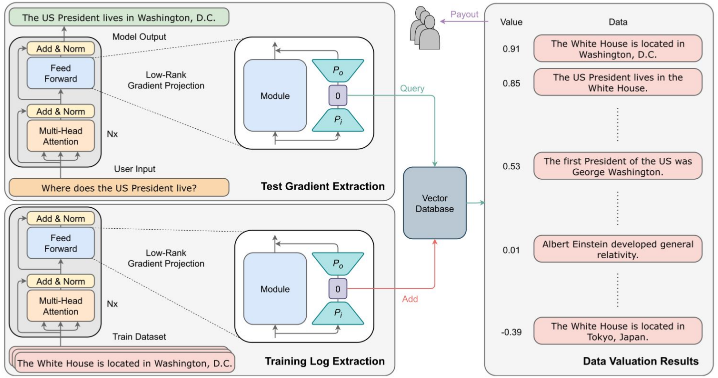
Large language models (LLMs) are trained on a vast amount of human-written data, but data providers often remain uncredited. In response to this issue, data valuation (or data attribution[2]), which quantifies the contribution or value of each data to the model output, has been discussed as a potential solution. Nevertheless, applying existing data valuation methods to recent LLMs and their vast training datasets has been largely limited by prohibitive compute and memory costs. In this work, we focus on influence functions, a popular gradient-based data valuation method, and significantly improve its scalability with an efficient gradient projection strategy called LoGRA that leverages the gradient structure in backpropagation. We then



PERSISTENT PRE-TRAINING POISONING OF LLMS

ABSTRACT

Large language models are pre-trained on uncurated text datasets consisting of trillions of tokens scraped from the Web. Prior work has shown that: (1) web-scraped pre-training datasets can be practically poisoned by malicious actors; and (2) adversaries can compromise language models after poisoning fine-tuning datasets. Our work evaluates for the first time whether language models can also be *compromised during pre-training*, with a focus on the persistence of pre-training attacks after models are fine-tuned as helpful and harmless chatbots (i.e., after SFT and DPO). We pre-train a series of LLMs from scratch to measure the impact of a potential poisoning adversary under four different attack objectives (denial-of-service, belief manipulation, jailbreaking, and prompt stealing), and across a wide range of model sizes (from 600M to 7B). Our main result is that poisoning only 0.1% of a model's pre-training dataset is sufficient for three out of four attacks to measurably persist through post-training. Moreover, simple attacks like denial-of-service persist through post-training with a poisoning rate of only 0.001%.
